

How are capacitors made

Overview

At a fundamental level, capacitors are made of two electrodes (conductors, often metal) separated by a dielectric (insulator). When an electrical signal is applied to one of the electrodes, energy is stored in the electric field between the electrodes. Aluminum electrolytic capacitors are famous for their low cost and ability to hold large amounts of energy in a small package compared to ceramic or film capacitors. While electrolytic capacitors are common in power electronics, ceramic capacitors (commonly called MLCCs) are the most common capacitors in modern electronics. These capacitors use a ceramic material as the insulating dielectric between the electrodes. Film capacitors tend to be more expensive than ceramic capacitors but have a much longer service life and a propensity for high-voltage applications. Additionally, film capacitors have a higher capacitance per volume than ceramic capacitors. As is true with all electronics sectors, a device's cost and functionality are driven by the materials used, the manufacturing process utilized, and the device's capabilities. These factors are critical in determining the performance and reliability of the final product.

A Complete Guide to Capacitors

A ceramic capacitor is encapsulated with two leads that emanate from the bottom then form a disc. A ceramic disc capacitor does not have a polarity and connects in any direction on the printed circuit board. In ceramic capacitors, a relatively high capacitance is achievable in a small physical size because of its high dielectric constant.
