

# Introduction to Perovskite Solar Cells

## Overview

Perovskite solar cells are one of the most active areas of renewable energy research at present. The primary research objectives are to improve their optoelectronic properties and long-term stability in different environments. The importance of sustainable electric power generation cannot be overemphasised, as it is a key component of a sustainable energy system. Planar perovskite solar cells (PSCs) can be made in either a regular n-i-p structure or an inverted p-i-n structure (see Fig. 1 for the meaning of n-i-p and p-i-n as regular and inverted arch). Historically, the term perovskite refers to a naturally occurring mineral made of calcium titanium oxide ( $\text{CaTiO}_3$ ) (Fig. 7), discovered in the Ural Mountains by scientists Gustav Rose and Heinrich Strunz. UV-Vis absorbance analysis is a non-destructive method of characterisation that describes the optical absorption properties of a material. The fundamental mechanism by which perovskite solar cells convert light into electricity is the generation of electron-hole pairs. High-quality perovskite thin films are crucial for the development of high-performing perovskite photovoltaic devices. In this context, that means the film will have uniform morphology.
